## ABSTRACT

Numerous efforts have been made to design the cathode of Li-S batteries to enhance reversible capacity and long-term cycling stability. However, challenges remain in achieving high electronic/ionic conductivity and suppressing the shuttle effect, especially for cathodes with high sulfur loading. Here we report a 3D free-standing hierarchical structure of VO<sub>2</sub>(P) (paramontroseite VO<sub>2</sub>) nanoparticles grown on nitrogen-doped carbon nanotube (NCNT) arrays as a catalytic host for high-performance sulfur cathodes. In this architecture, the VO<sub>2</sub>(P) nanoparticles function as catalysts to oxidize the LiPS to produce thiosulfate due to the strong chemical interaction. Furthermore, thiosulfates act as a mediator to catenate long-chain LiPS together and convert short-chain Li<sub>2</sub>S<sub>2</sub>/Li<sub>2</sub>S and surface-bound polythionate complexes. Accordingly, the VO<sub>2</sub>(P)-NCNT/S cathode exhibits excellent performance with high discharge capacity output ( $\approx 1200 \text{ mA h g}^{-1}$  at 0.2 C), stable long-term cycling ( $\approx 67\%$  retention at 2 C for 500 cycles), and high sulfur loading cycling (initial areal capacity of  $10.2 \text{ mA h cm}^{-2}$  at 0.2 C for 200 cycles). This nanostructure catalytic cathode with high sulfur loadings, as well as stable cycling performances, is attractive for developing practically useable Li-S batteries.

## 1. Introduction

The lithium-sulfur (Li-S) battery is one of the most promising alternatives to the prevailing conventional lithium-ion batteries (LIBs) to meet the ever-increasing demands for high energy density, low cost, and high safety of energy storage systems [1,2]. Li-S batteries could supply a high theoretical capacity of  $1675 \text{ mA h g}^{-1}$  (10 times higher than that of LIBs) and a high theoretical energy density of  $2567 \text{ kW kg}^{-1}$  (5 times higher than that of LIBs). Meanwhile, elemental sulfur is nontoxic and widely accessible at a low cost which is essential for meeting energy conservation and sustainable development standards. However, the practical application of state-of-the-art Li-S batteries is still hindered by significant challenges such as low sulfur utilization, poor Coulombic efficiency, fast capacity degradation, severe self-discharge, and short cycle life due to the intrinsically low electronic conductivity of sulfur and lithium polysulfide (LiPS) shuttle reactions [3,4].

Different carbon materials have been reported as the host to as hosts

to immobilize sulfur [1,5–8]. However, normal carbon materials always have a nonpolar surface, which is hardly to trap and restrict LiPS shuttle reactions. In contrast, nanostructured inorganic compounds have a strong chemical affinity with LiPS and prevent the diffusion of LiPS more effectively than carbon materials [9]. Even so, both these materials depend on physical or chemical adsorption to prevent LiPS shuttling and are merely palliative solutions which do not address the fundamental problems.

An alternative strategy to suppress the shuttle effect is to convert LiPS into insoluble Li<sub>2</sub>S<sub>2</sub>/Li<sub>2</sub>S to minimize their dissolution and diffusion into the electrolyte [7]. Recent studies have shown that many polar hosts, such as metal oxides [10–16], metal sulfides [17–21], metal nitrides [22–24], metal carbide [25], and some metal-free materials [26–31] not only have a strong affinity to LiPS but also catalytically promote the conversion of LiPS to solid Li<sub>2</sub>S<sub>2</sub>/Li<sub>2</sub>S. Nazar et al. proposed a way to entrap LiPS in the cathode relies on MnO<sub>2</sub> nanosheets binding and reacting with higher-order LiPS to convert them on reduction to insoluble lithium sulfide via disproportionation [11].

Zhang et al. utilized the interface between  $\text{CoS}_2$  and the electrolyte, which served as strong adsorption and activation sites for polar polysulfides to accelerate redox reactions of LiPS [17]. Lee et al. demonstrated the effectiveness of  $\text{MoS}_2$ -x/rGO as a catalyst for LiPS conversion in a sulfur cathode, in which the surface sulfur deficiencies participated in the LiPS conversion and improved the kinetics of LiPS redox reactions [18]. Yang et al. reported a twinborn  $\text{TiO}_2$ -TiN heterostructure electrode that achieves a smooth trapping-diffusion-conversion of LiPS across the interface [22].

Vanadium dioxides with a series of different polymorphs such as  $\text{VO}_2(\text{A})$ ,  $\text{VO}_2(\text{B})$ ,  $\text{VO}_2(\text{C})$ ,  $\text{VO}_2(\text{R})$ , and  $\text{VO}_2(\text{M})$  and mineral phases such as paramontroseite and nsutite-type  $\text{VO}_2$  have received great interest in device applications owing to its unique metal-insulator transition with abundant structural phases, low cost, and controllable morphologies [32–34]. Nazar et al. report a metastable  $\text{VO}_2(\text{B})$  with high chemical reactivity to anchor LiPS, which has a redox potential that lies just above the typical redox potential range ( $> 2.4$  V) of soluble LiPS [35]. Fan et al. construct a  $\text{VO}_2(\text{B})$ -VN binary host, accomplishing smooth immobilization-diffusion-conversion of LiPS to improve the electrochemical performance of Li-S batteries [36]. However, the  $\text{VO}_2(\text{B})$  is metastable and tends to transition into the  $\text{VO}_2(\text{A})$  phase under  $160^\circ\text{C}$  and  $\text{VO}_2(\text{M})$  under  $300^\circ\text{C}$  [37,38]. Moreover,  $\text{VO}_2(\text{B})$  shows semiconductor characteristics with low intrinsic electrical conductivity [39], which will hinder the catalytic conversion of LiPS by  $\text{VO}_2(\text{B})$  [36].

Paramontroseite vanadium dioxide ( $\text{VO}_2(\text{P})$ ), a minor structure, was first discovered in minerals during the 1950s [40]. The  $\text{VO}_2(\text{P})$  is composed of infinite chains along the c-axis with nearest V–V distances of 0.293 nm, in which d-orbital electrons would be shared by all of the metal V atoms along the c-axis in paramontroseite similar to that in metallic rutile  $\text{VO}_2(\text{R})$  [32]. Among the family of  $\text{VO}_2$ , the  $\text{VO}_2(\text{P})$  was revealed to have the most promising electrical conducting properties at room temperature from the structural and its calculation results. However, few references have reported its application in energy storage devices due to the hindered synthetic route [41]. To the best of our knowledge, our work is the first to introduce  $\text{VO}_2(\text{P})$  into a Li-S battery host.

Herein, we present NCNTs vertically grown on carbon paper as a free-standing carbon-based host onto which the  $\text{VO}_2(\text{P})$  nanoparticles and sulfur are uniformly deposited for use as a cathode material, henceforth abbreviated as the  $\text{VO}_2(\text{P})$ -NCNT host. The 3D structure with vertically aligned NCNTs have a high surface area and enable uniform distribution of sulfur for high sulfur loading while also facilitating the electron/ion transport between the sulfur and host to improve cathode conductivity. In addition,  $\text{VO}_2(\text{P})$  nanoparticles are also uniformly distributed and could effectively enhance the charge transfer and redox reaction kinetics as a catalytic mediator. This  $\text{VO}_2(\text{P})$ -NCNT/S cathode has stable long-term cycling life (over 500 cycles with 67% retention) under a high rate of 2 C. This cathode with high sulfur loading (up to  $9.6\text{ mg cm}^{-2}$ ) also demonstrates its superior performance. Furthermore, the mechanisms of enhancing redox kinetics and catalysis of LiPS conversion with  $\text{VO}_2(\text{P})$  are also discussed.

## 2. Experimental section

### 2.1. Preparation of free-standing NCNT host

The NCNT free-standing cathode was prepared by using a spray pyrolysis chemical vapor deposition (SPCVD) method, as described previously [42]. A piece of carbon paper (CP) was sputtered with aluminum as the buffer layer. The CP was then fixed inside a vertical quartz tube of a chemical vapor deposition furnace. The furnace was heated up to  $850^\circ\text{C}$  in 20 min under Ar with the flow rate of 240 sccm. After the temperature reached  $850^\circ\text{C}$ , a catalytic solution A (1 g ferrocene in 50 mL acetonitrile) was introduced into the tube under an ultrasonic probe sonicator at a flow rate of  $250\ \mu\text{L}/\text{min}$  for 6 min. Then, a solution B (10 g imidazole in 50 mL acetonitrile) was introduced into

the tube under the same condition for  $\sim 35$  min. After the SPCVD process, the NCNT arrays were grown vertically on the surface of the CP.

### 2.2. Preparation of free-standing $\text{VO}_2(\text{P})$ -NCNT host

The  $\text{VO}_2(\text{P})$ -NCNT host was prepared by using a facile hydrothermal method, as described elsewhere [39]. In a typical synthesis, 1.6 mmol  $\text{Na}_3\text{VO}_4$  and 8 mmol thioacetamide (TAA) were dissolved in 40 mL distilled water with continuous stirring to form a homogeneous solution. And then 4 mmol  $\text{NH}_4\text{F}$  was also added into the as-obtained solution to adjust the pH. Then this solution was transferred into a 50 mL Teflon-lined autoclave together with the free-standing NCNT-CP, which was sealed and heated at  $180^\circ\text{C}$  for 20 h. After the hydrothermal process, the  $\text{VO}_2(\text{P})$ -NCNT free-standing cathode was alternately washed with ethanol and distilled water 3 times, and finally dried in an  $120^\circ\text{C}$  vacuum oven. To control the morphology of the  $\text{VO}_2(\text{P})$  nanoparticles,  $\text{VO}_2(\text{P})$ -NCNT cathodes with different contents of precursors (0.6, 1.1, and 2.1 mmol  $\text{Na}_3\text{VO}_4$ ; 3, 5.5, 10.5 mmol TAA) are also prepared.

### 2.3. Preparation of $\text{VO}_2(\text{P})$ -NCNT/S cathode

The sulfur active material was introduced into the free-standing hosts by controlled drop casting sulfur solution in  $\text{CS}_2$  (100 mg sulfur in 5 mL  $\text{CS}_2$ ), giving sulfur cathodes of  $\text{VO}_2(\text{P})$ -NCNT/S and NCNT/S. To uniformly distribute sulfur in the  $\text{VO}_2(\text{P})$ -NCNT/S cathode, the same process was repeated several times. Finally, the  $\text{VO}_2(\text{P})$ -NCNT/S cathodes were dried in a vacuum oven at  $60^\circ\text{C}$  for 6 h. The regular sulfur loading is about  $2.0\text{ mg cm}^{-2}$ . The cathodes with high areal sulfur loadings of 6.4 and  $9.6\text{ mg cm}^{-2}$  were also prepared to test the stability of cycling performances.

### 2.4. Adsorption properties of lithium polysulfides

$\text{Li}_2\text{S}_4$  and  $\text{Li}_2\text{S}_6$  solutions were prepared by mixing  $\text{Li}_2\text{S}$  and S with a molar ratio of 1:3 and 1:5, respectively, into a 1:1 (v/v) DOL/DME mixture, and stirred overnight at  $60^\circ\text{C}$ . 4 mg of NCNT or  $\text{VO}_2(\text{P})$ -NCNT powder was exfoliated from the hosts and added into 2 mL of a  $4\text{ mmol L}^{-1}$   $\text{Li}_2\text{S}_4$  stock solution. Similarly, 6 mg of NCNT or  $\text{VO}_2(\text{P})$ -NCNT powder were added into 3 mL of a  $5\text{ mmol L}^{-1}$   $\text{Li}_2\text{S}_6$  stock solution. The mixtures were stirred to facilitate adsorptions.

### 2.5. Preparation of $\text{VO}_2(\text{P})$ -NCNT@ $\text{Li}_2\text{S}_4$

In an Ar-filled glovebox, a piece of  $\text{VO}_2(\text{P})$ -NCNT host was soaked in a solution containing 1 mmol  $\text{Li}_2\text{S}_4$  in 5 mL dimethyl ether (DME) for 12 h. The host was then washed and dried in a glovebox.

### 2.6. Materials characterization

The morphologies were characterized using scanning electronic microscopy (FESEM, Hitachi S-4800) and scanning transmission electron microscopy (STEM, FEI Talos F200X). X-ray photoelectron spectroscopy (XPS, ESCALAB 250Xi) with focused monochromatized Al K $\alpha$  radiation (1486.6 eV) was used to analyze the elemental composition and valence state. X-ray diffraction (XRD, Bruker D8 advanced) with Cu K $\alpha$  radiation ( $\lambda = 1.5415\ \text{\AA}$ ) and Raman spectroscopy (HORIBA Scientific LabRAM) with 632.8 nm HeNe laser were used to analyze the structure, composition and chemical bonds of these samples. The nitrogen sorption isotherm was recorded on a gas sorptometer (Micromeritics 3Flex 3500). Thermogravimetric analysis (TGA, TA SDT Q600) was performed in air at a heating rate of  $5^\circ\text{C min}^{-1}$ . X-ray absorption near edge structure (XANES) spectra of sulfur K-edge and vanadium K-edge were measured on the Soft X-ray Microcharacterization beamline (SXRMB) at the Canadian Light Source (CLS) in Saskatoon. To avoid the contamination of samples, all the samples were sealed using Kapton tape in an argon-filled glove box.

## 2.7. Symmetrical cell assembly and measurements

The electrodes for symmetrical cells were fabricated without the presence of elemental sulfur. VO<sub>2</sub>(P)-NCNT disks were used as identical working and counter electrode with 60 μL electrolyte (0.5 mol L<sup>-1</sup> Li<sub>2</sub>S<sub>6</sub> and 1 mol L<sup>-1</sup> LiTFSI dissolved in DOL/DME (v/v = 1/1)). Cyclic voltammetry (CV) measurements of the symmetrical cells were performed at a scan rate of 50 mV s<sup>-1</sup> between -1.0 V and 1.0 V.

## 2.8. Electrochemical characterization

Standard CR2032-type coin cells were assembled in an Ar-filled glove box with oxygen and moisture content below 1 ppm. The electrolyte was 1.0 M lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) dissolved in mixed solvent of 1,3-dioxolane (DOL) and DME (v/v = 1:1) with 1 wt% of LiNO<sub>3</sub> as an additive. The amount of electrolyte used in a coin cell is about 80–120 μL. The galvanostatic charge/discharge tests and galvanostatic intermittent titration technique (GITT) of the cells were measured on a Land T2001A battery testing station with a voltage range of 1.7–2.8 V. Through a VMP3 electrochemical workstation, cyclic voltammetry (CV) was performed at a scan rate of 0.1 mV s<sup>-1</sup> and electrochemical impedance spectroscopy (EIS) was tested with a frequency range of 100 kHz to 0.1 Hz.

## 3. Results and discussion

### 3.1. Materials characterization

The synthesis of the VO<sub>2</sub>(P)-NCNT composite host is illustrated in Fig. 1a. The free-standing NCNT collector was prepared on carbon paper (CP) through a two-step method, as described elsewhere [42]. The CP substrate exhibits a 3D structure composed of randomly oriented carbon fibers with a diameter of ~10 μm (Fig. S1). A uniform layer of NCNTs of approximately 40 μm in length is grown on the CP, covering the carbon fibers (Fig. S2), followed by the deposition of uniform VO<sub>2</sub>(P) nanoparticles with an average particle size of ~120 nm (Fig. 1b–d) via a facile hydrothermal method. The size and amount of the particles are controlled by the concentration of the precursors. The FESEM images of the four samples with increased precursor concentrations resulting in different morphologies are shown in Fig. S3. The free-standing and flexible features of this 3D structured VO<sub>2</sub>(P)-NCNT host are also shown in Fig. S4. The elemental mapping images suggested the uniform concentration distributions in large scale (Fig. S5).

The TEM micrographs of NCNTs display their characteristic bamboo-like features with a stacked cone structure (Fig. 1e). The uniform growth of spherical VO<sub>2</sub>(P) nanoparticles with a diameter of ~120 nm on NCNTs can also be observed (Fig. 1b–d). The TEM images with selected-area electron diffraction (SAED) pattern were used to investigate the VO<sub>2</sub>(P) nanoparticles grown on NCNT (Fig. 1f–g). The distances between adjacent lattice planes (d-spacing) were measured to be ~0.234 nm, corresponding to the (111) plane of orthorhombic phase of paramontroseite VO<sub>2</sub>, which is in good agreement with the SAED pattern (Fig. 1h) [41]. Energy dispersive X-ray (EDS) mapping images (Fig. 1i–m) with the distributions of V, O, and C suggested an atomic concentration gradient of VO<sub>2</sub>(P) on the surface of the NCNT arrays with high uniformity. Similarly, the EELS elemental mappings are consistent with this result (Fig. S6).

XRD, Raman, XPS, and TGA/DSC measurements were performed to determine the detailed phase and composition of the VO<sub>2</sub>(P)-NCNT sample. Fig. 2a shows the XRD patterns of the pure NCNT and VO<sub>2</sub>(P)-NCNT, where the broad diffraction peaks at 26.5° and 43.2° agree well with the (002) and (004) planes of graphitic carbon (JCPDS 75-1621). For VO<sub>2</sub>(P)-NCNT, apart from the peaks of NCNT, all the main peaks correspond to the orthorhombic phase of VO<sub>2</sub>(P) with a space group of I2/c (JCPDS 73-0514) [41]. The super-cell structure of orthorhombic

VO<sub>2</sub>(P) projected along different orientations are shown in Fig. 2b and Fig. S7. In Fig. 2c, the intense peaks that appear between 150 and 1200 cm<sup>-1</sup> are indexed well within the fingerprint region of the paramontroseite minor (RRUFF database: R050391). The D-band and G-band at ~1310 and ~1590 cm<sup>-1</sup>, derived from NCNT, represent defect-induced vibrations of disordered carbon and vibration of the sp<sup>2</sup> bonded carbon atoms, respectively [43,44]. The XPS spectra of V 2p and O 1s peaks for the sample are shown in Fig. 2d. The V 2p<sub>3/2</sub> and V 2p<sub>1/2</sub> peaks at 516.6 and 524.0 eV correspond to V<sup>4+</sup> in paramontroseite, and the corresponding spin-orbit splitting energy is 7.4 eV [45]. The tiny peaks of V 2p at 515.3 and 522.8 eV may derived from the trace amount of V<sup>3+</sup> in V<sub>2</sub>O<sub>3</sub>. The peaks at 531.3, 530.0 and 519 eV are assigned to the O-H, O<sup>2-</sup> and X-ray satellite groups, respectively [46]. The TGA/DSC curves of pure NCNT, VO<sub>2</sub>(P), VO<sub>2</sub>(P)-NCNT samples are shown in Fig. 2e. A weight increase of ~8.1 wt% over 300–550 °C in VO<sub>2</sub>(P) could be associated with the oxidation process from VO<sub>2</sub> to V<sub>2</sub>O<sub>5</sub> [47]. There is an endothermic peak at ~670 °C, which may be due to the melting point of V<sub>2</sub>O<sub>5</sub> [38]. For the pure NCNT, there is another exothermic process with a weight loss of ~75 wt% at 350–500 °C (peak at 462 °C), which derives from the burning of NCNT. The nitrogen adsorption/desorption isotherm of the NCNT (Fig. 2f) shows a mixed shape of type II (at medium pressures) and type IV (at higher pressures) [42]. The BET surface area and total pore volume of pure CP, pure NCNT, VO<sub>2</sub>(P)-NCNT hosts were determined to be 0.3, 37.0 and 21.3 m<sup>2</sup> g<sup>-1</sup>, respectively. It should be noted that the BET surface area of VO<sub>2</sub>(P)-NCNT exhibit more than 70 times than that of pure CP, thus could provide a much larger surface area to load much higher sulfur weight per unit area.

### 3.2. Electrochemical performance

Standard CR2032-type coin cells with Li metal as a counter electrode were assembled to measure the electrochemical performance of the VO<sub>2</sub>(P)-NCNT/S cathode. In Fig. 3a, the cycling performances of VO<sub>2</sub>(P)-NCNT/S and NCNT/S were examined at a current density of 0.2 C (1 C = 1672 mAh<sup>-1</sup>). For the VO<sub>2</sub>(P)-NCNT/S cathode, it delivers a stable cycling performance with a high reversible discharge capacity of ~1200 mAh g<sup>-1</sup>. The capacity retention is above 94% after 100 cycles (compared to the 2nd cycle). For the pure NCNT/S cathode, the discharge capacity fades gradually and the capacity retention is only 63.3% after 100 cycles (compared to the 2nd cycle). To further compare the electrochemical performances, the rate capabilities of the VO<sub>2</sub>(P)-NCNT/S and NCNT/S cathodes were measured under a stepwise current density program from 0.1 C to 2 C (Fig. 3b). The corresponding galvanostatic charge/discharge tests were shown in Fig. S8. The average reversible capacities of NCNT/S are 1030, 790, 765, 775, 680, 603, and 395 mA h g<sup>-1</sup> at rates of 0.1, 0.2, 0.4, 0.6, 0.8, 1 and 2 C, respectively. However, the VO<sub>2</sub>(P)-NCNT/S cathode shows significant high-rate improvement, with average reversible capacities of 1100, 982, 910, 886, 875, 864, and 760 mA h g<sup>-1</sup> at rates of 0.1, 0.2, 0.4, 0.6, 0.8, 1 and 2 C, respectively, which is stable at the same current density. When the current density is returned to 0.2 C, the capacity can recover to a similar value of the initial step at 0.2 C. The better rate performance of VO<sub>2</sub>(P)-NCNT/S indicates that the VO<sub>2</sub>(P) nanoparticles play a key role in improving the rate performances due to the high conductivity in the composite host.

The cycling stability of the VO<sub>2</sub>(P)-NCNT/S cathode was also investigated at 2 C for 500 cycles in Fig. 3c. The cathode maintains stable cycling performance with a reversible discharge capacity of ~880 mA h g<sup>-1</sup>, which corresponds to a capacity retention of ~67% from the 2nd cycle. Even after 500 cycles, the cathode still delivers a high reversible discharge capacity of 780 mA h g<sup>-1</sup>, while the capacity of NCNT/S cathode fades to 280 mA h g<sup>-1</sup> after only 260 cycles (retaining 28.8% of its capacity of the 2th cycle). The higher reversible capacity and capacity retention of the VO<sub>2</sub>(P)-NCNT/S cathode confirm the important role of the VO<sub>2</sub>(P) in this 3D architecture. Figs. S9 and

**Fig. 1.** (a) Schematic illustration of the synthesis of the  $\text{VO}_2(\text{P})$ -NCNT host; (b–d) FESEM images (e–g) TEM images and SAED pattern; (h) FFT pattern corresponding to (g); (i–m) STEM EDX mapping images of the  $\text{VO}_2(\text{P})$ -NCNT host.

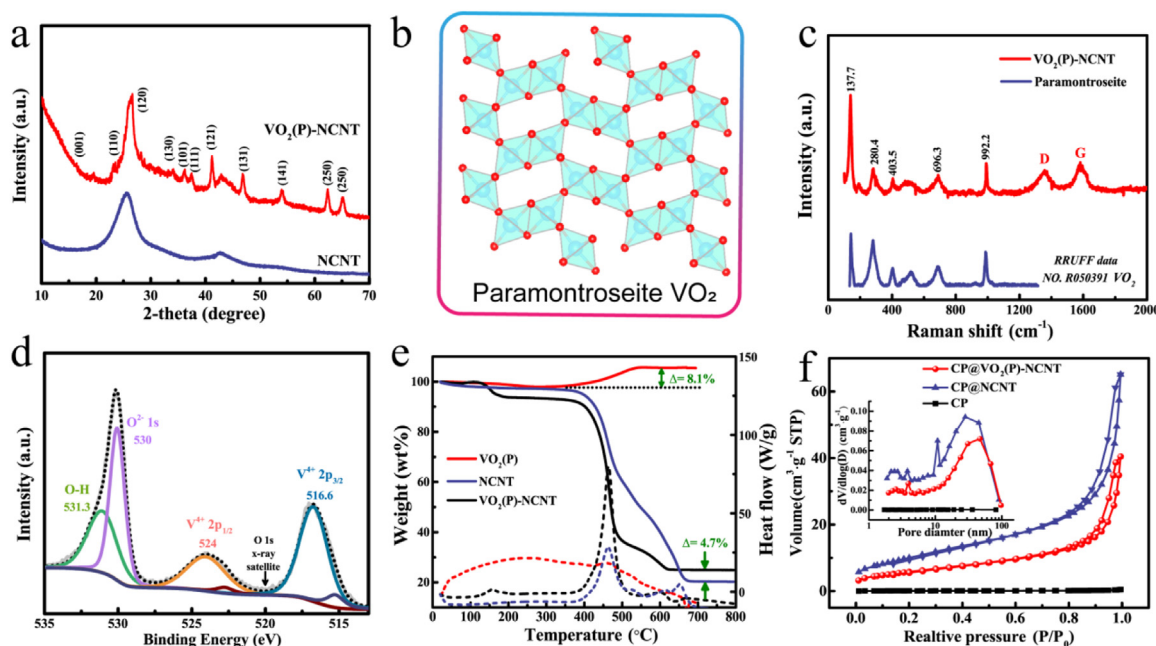

**S10** show the FESEM images and corresponding EDX mapping images of  $\text{VO}_2(\text{P})$ -NCNT/S cathode after 500 cycles at 2.0 C. The  $\text{VO}_2(\text{P})$ -NCNT/S cathode after long-term cycling still maintain the original morphology of  $\text{VO}_2(\text{P})$  nanoparticles on NCNT, suggesting high structural stability of the  $\text{VO}_2(\text{P})$ -NCNT host.

Despite the remarkable progress made on cycling stability, it should be noted that almost all the long-term cycling performance is achieved with low areal loading sulfur cathodes (usually  $< 2.0 \text{ mg cm}^{-2}$ ) [48]. Thus, it is important to attain cathodes with high areal loading ( $> 4.0 \text{ mg cm}^{-2}$ ) and long-term cycling life ( $> 500$  cycles) to meet real applications of Li-S batteries. In Fig. 3d, the  $\text{VO}_2(\text{P})$ -NCNT/S cathode with a sulfur loading of  $4.8 \text{ mg cm}^{-2}$  shows a high reversible capacity of  $\sim 450 \text{ mg cm}^{-2}$  and stable cycling performance with a decay rate of about 0.09% per cycle. The electrochemical performance of  $\text{VO}_2(\text{P})$ -NCNT/S cathodes with high areal loading of 6.4 and  $9.6 \text{ mg cm}^{-2}$  were also tested (Fig. 3e and Fig. S11). The corresponding galvanostatic charge/discharge tests were shown in Fig. S12. The  $\text{VO}_2(\text{P})$ -NCNT with sulfur loadings of 6.4 and  $9.6 \text{ mg cm}^{-2}$  at 0.2 C show high initial areal

capacities of 7.8 and  $10.2 \text{ mAh cm}^{-2}$ , respectively. It worth noting that the  $\text{VO}_2(\text{P})$ -NCNT/S cathode of 6.4 and  $9.6 \text{ mg cm}^{-2}$  maintain high areal capacities of 4.8 and  $5.7 \text{ mAh cm}^{-2}$  even after 200 cycles, which are larger than the standard for commercial Lithium-ion batteries ( $4 \text{ mAh cm}^{-2}$ ). Performance comparisons with recent work on vanadium-based cathodes in Li-S batteries are shown in Fig. 3f [23,24,35,49–54]. Our work shows as one of the best results reported to date (Table S1). The high sulfur loading  $\text{VO}_2(\text{P})$ -NCNT/S cathode with high cycling stability and large areal capacity demonstrates its excellent electrochemical performance as a composite host for Li-S batteries.

### 3.3. Redox kinetics characterizations

Fig. 4a and Fig. S13 display the cyclic voltammograms (CV) of  $\text{VO}_2(\text{P})$ -NCNT/S and NCNT/S with the same sulfur loading at a scan rate of  $0.1 \text{ mV s}^{-1}$ , which exhibit the characteristic lithiation/delithiation features of sulfur cathodes. Compared to the NCNT/S cathode,  $\text{VO}_2(\text{P})$ -NCNT/S shows an obvious shift to a higher potential in the

**Fig. 2.** (a) XRD patterns; (b) schematic illustration of orthorhombic paramontroseite  $\text{VO}_2$  projected along  $[001]$ ; (c) Raman spectra; (d) XPS spectra; (e) TGA/DSC curves, and (f)  $\text{N}_2$  adsorption-desorption curves and analysis of the  $\text{VO}_2(\text{P})$ -NCNT host.

lithiation (discharge) sweep and a negative shift to a lower potential in the delithiation (charge) sweep, indicating a decrease of cell polarization [55]. The potential shifts in charge/discharge sweeps suggest that the redox kinetics reactions in the Li-S battery have been improved by the  $\text{VO}_2(\text{P})$ . The Tafel plots (Fig. S14) and corresponding onset potentials and exchange current densities (Fig. 4b) are determined by potentiostatic polarization experiments [55,56]. The higher onset potential values in the lithiation process and lower values in the delithiation process indicate more favorable reaction kinetics occurring in the  $\text{VO}_2(\text{P})$ -NCNT/S cathodes. Additionally, the larger exchange current densities of  $\text{VO}_2(\text{P})$ -NCNT/S cathodes also indicates that the  $\text{VO}_2(\text{P})$  nanoparticles could effectively accelerate the charge transfer and redox reaction.

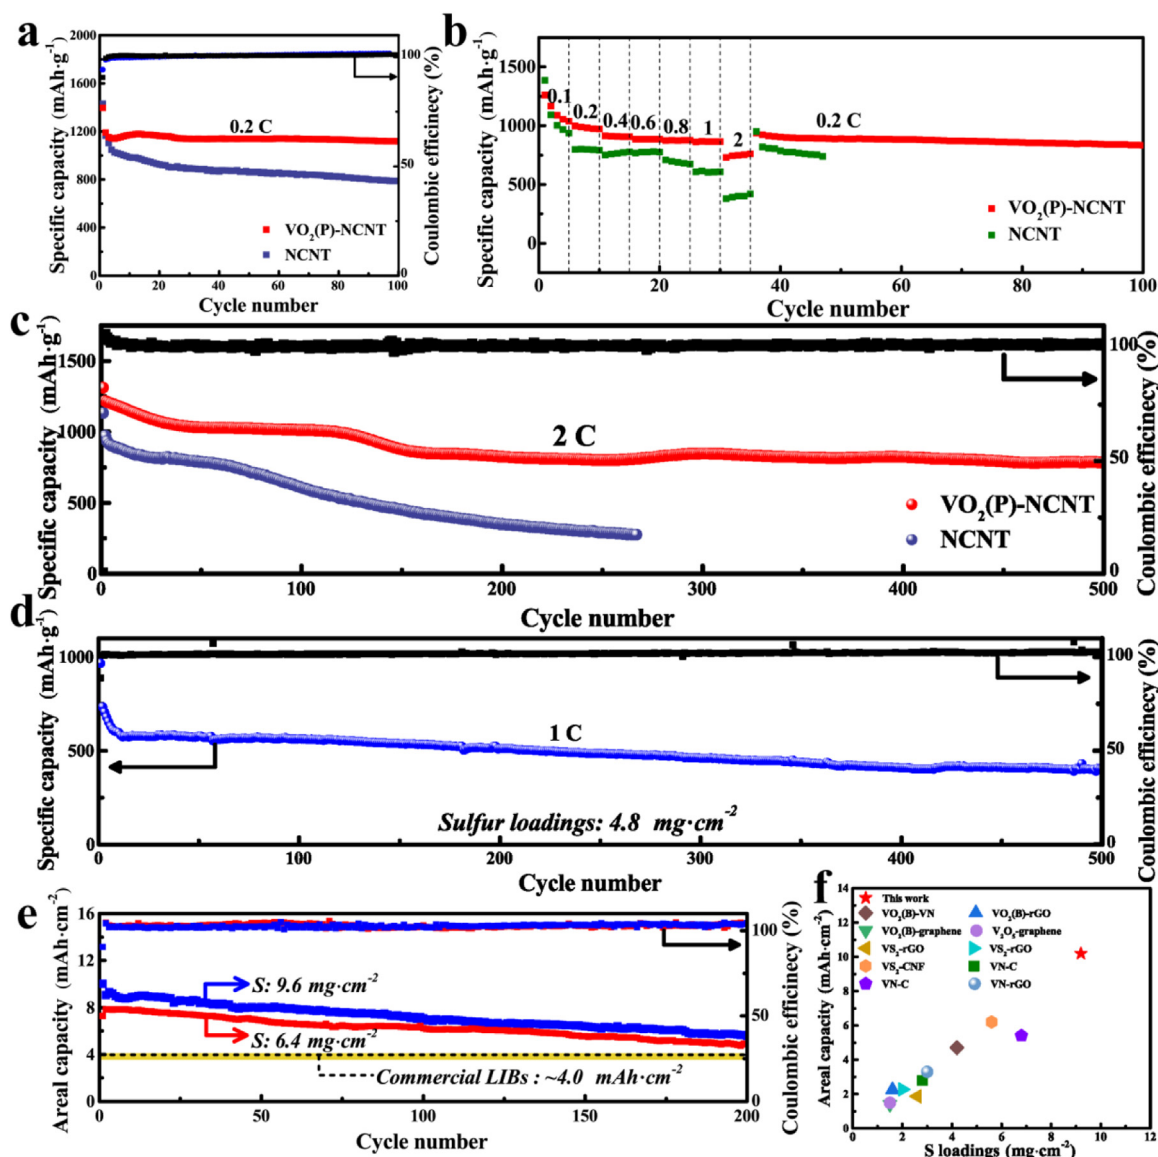

To analyze the  $\text{VO}_2(\text{P})$  on the improvement of the redox kinetics during cycling, the Nyquist plots before/after cycling are measured (Fig. 4c). The Nyquist plots were fitted with an equivalent circuit (inset of Fig. 4b) and the fitting results are summarized in Table S1. The first intercept (at high frequency) corresponds to the electrolyte resistance ( $R_s$ ). The curve at high frequency is ascribed to Li-ion diffusion through the surface of nanolayers ( $R_{\text{surf}}$ ), the curve at medium frequency is assigned to charge transfer ( $R_{ct}$ ) and double-layer capacitance ( $C_{dl}$ ) [57]. The Ohmic resistance of  $\text{VO}_2(\text{P})$ -NCNT/S and NCNT/S cathodes before/after cycling are similar. In addition, the  $\text{VO}_2(\text{P})$ -NCNT/S before/after cycling (41.8/87.1  $\Omega$ ) shows a smaller charge transfer resistance than those of NCNT/S (51.7/111.8  $\Omega$ ). More importantly,  $R_{\text{surf}}$  of the  $\text{VO}_2(\text{P})$ -NCNT/S (23.6  $\Omega$ ) after cycling is much smaller than that of the pure NCNT/S (75.2  $\Omega$ ), demonstrating that the  $\text{VO}_2(\text{P})$  facilitates Li-ion diffusion from the electrolyte to the electrode surface. The slope of the linear fitting plot of  $Z'$  versus  $\omega^{-1/2}$  defines the Warburg factor, which reflects the solid-state diffusion of ions inside the electrode materials (see Supporting information for details) [43]. Before cycling, both  $\text{VO}_2(\text{P})$ -NCNT/S and NCNT/S show similar slopes in Fig. 4d. After cycling, the increased slope of the NCNT/S cathode indicates the decreased ion diffusion coefficient. In contrast,  $\text{VO}_2(\text{P})$ -NCNT/S still has a small slope. Therefore, it can be concluded that  $\text{VO}_2(\text{P})$  plays a key role in maintaining fast ion diffusion kinetics.

To operate the cell under almost quasi-equilibrium conditions, the GITT curves are measured for the 1st cycle (Fig. 4e). In a typical process, a current pulse of 0.05 C was applied for 30 min to measure the

closed-circuit-voltage (CCV), and then resting for 1 h to obtain the quasi-open-circuit-voltage (QOCV). Compared with the pure NCNT/S, the charge/discharge plateaus of  $\text{VO}_2(\text{P})$ -NCNT/S are longer and flatter, thus demonstrating larger capacities. In addition,  $\text{VO}_2(\text{P})$ -NCNT/S shows lower oxidation voltage plateaus and decreased hysteresis ( $\Delta E$ , voltage gap between oxidation and reduction plateaus), which further reveal the accelerated redox kinetics of  $\text{VO}_2(\text{P})$ -NCNT/S cathode. To analyze detailed variations during the charge/discharge process, the reaction resistances (R.R.) at different lithiation/delithiation stages were evaluated from the difference between CCV and QOCV (Fig. 4f) [45]. The R.R. of  $\text{VO}_2(\text{P})$ -NCNT/S are much lower than those of pure NCNT/S and are ascribed to the transfer reactions of  $\text{Li}_2\text{S}_x$  ( $x < 4$ ) to  $\text{Li}_2\text{S}$  in the discharge process and from  $\text{Li}_2\text{S}_x$  ( $x > 6$ ) to  $\text{S}_8$  in the charge process. These results suggest that  $\text{VO}_2(\text{P})$  accelerate the redox kinetics of LiPS conversions in  $\text{VO}_2(\text{P})$ -NCNT/S cathode.

To further identify the redox reaction mechanisms of the cathodes during the charge/discharge process, ex-situ XANES of S K-edge for NCNT and  $\text{VO}_2(\text{P})$ -NCNT hosts at different states of charge/discharge during the first cycle is shown in Fig. 5. For the S K-edge of NCNT, the intensity of the XANES peak corresponding to  $\text{S}_8$  at 2471.5 eV is decreased in the discharge process, which represents the transformation from  $\text{S}_8$  to LiPS (Fig. 5a). When discharged to 1.7 V, a low energy peak appears which is derived from the presence of LiPS ( $\text{Li}_2\text{S}_x$ ,  $x > 2$ ) and there is no evidence of the formation of insoluble  $\text{Li}_2\text{S}$ . The accumulation of LiPS in electrolyte causes severe shuttle movement to the anode to form non-reusable solid  $\text{Li}_2\text{S}_2/\text{Li}_2\text{S}$  and thus leads to the irreversible loss of active materials [58].

However, the S K-edge of  $\text{VO}_2(\text{P})$ -NCNT host shows a typical Li-S reaction process corresponding to the typical 2-plateau charge/discharge voltage profile of Li-S batteries in ether-based electrolytes (Fig. 5b). When discharged to 2.0 V, a typical LiPS peak appears at lower energy of  $\text{S}_8$  peak. After the voltage is discharged to 1.7 V, clear  $\text{Li}_2\text{S}$  peaks at 2471.6 and 2473.3 eV [57] form at higher energy of  $\text{S}_8$  peak (IV in Fig. 5b). These results indicate that the  $\text{VO}_2(\text{P})$  accelerate the transformations from the LiPS to insoluble  $\text{Li}_2\text{S}$ . In the charge process, the  $\text{Li}_2\text{S}$  retransform to LiPS at 2.3 V. It should be known that the transformation of insoluble  $\text{Li}_2\text{S}$  back to LiPS also requires a large activation energy because the aggregation during their formation process always leads to the slow reaction kinetics and low energy efficiency

**Fig. 3.** (a) Cyclic performance at 0.2 C for 100 cycles; (b) Rate capability curves at various current densities from 0.1 C to 2 C; (c) Long-term cycling performance at 2 C for 500 cycles of NCNT/S and VO<sub>2</sub>(P)-NCNT/S cathodes; (d) Long-term cycling performance at 1 C for 500 cycles of VO<sub>2</sub>(P)-NCNT/S cathodes with a high sulfur loading of 4.8 mg cm<sup>-2</sup>; (e) Areal capacities of VO<sub>2</sub>(P)-NCNT/S cathodes with high sulfur loadings of 6.4 and 9.6 mg cm<sup>-2</sup>; (f) Comparison of recent work on vanadium-based cathodes in Li-S batteries.

[9,59]. In addition, an S<sub>8</sub> peak with strong intensity was reformed when charged to 2.8 V, which suggests low consumption of active material and superior cycling performance. Even after 300 cycles, the S<sub>8</sub> peak could still be identified.

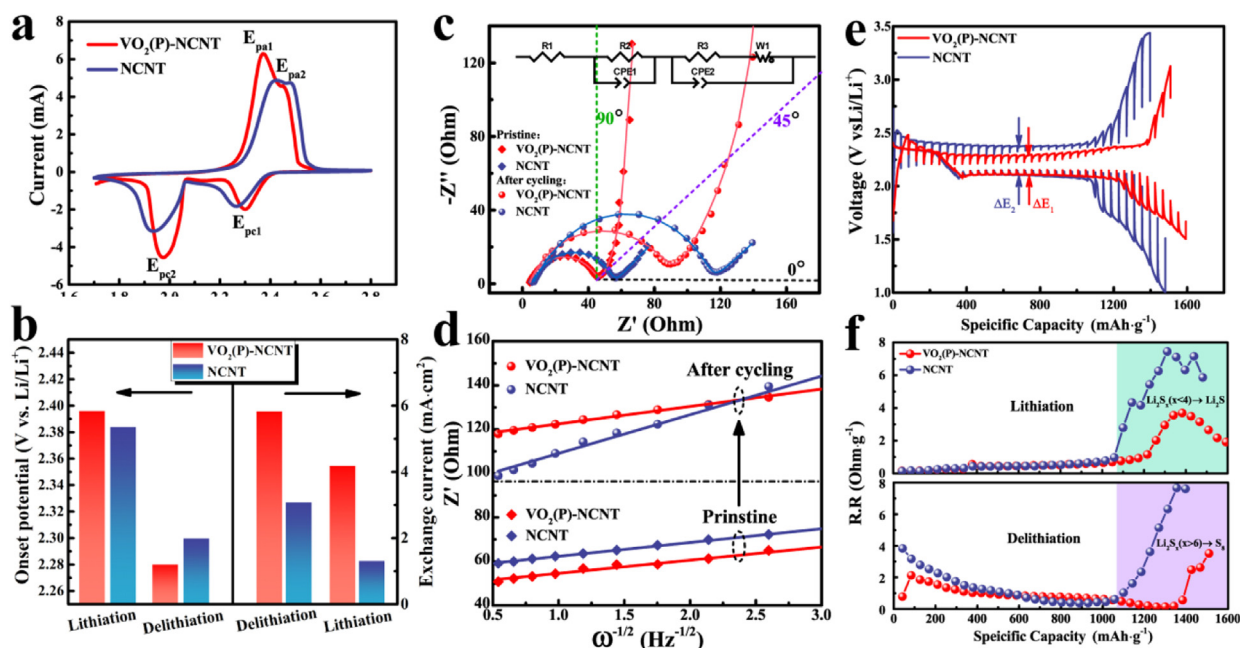

### 3.4. Polysulfides conversion characterizations

As LiPS shuttle reactions are the chief culprit for capacity fading and even the failure of Li-S batteries, constructing redox mediators to propel soluble LiPS conversion is one of the best choices to maintain stable electrochemical performance of Li-S batteries [9]. To test the interaction between VO<sub>2</sub>(P) and LiPS, Li<sub>2</sub>S<sub>4</sub>/DME and Li<sub>2</sub>S<sub>6</sub>/DME solutions were used to test LiPS adsorptions (Fig. 6a). After 30 min, the NCNT appeared to have no observable effect on the Li<sub>2</sub>S<sub>4</sub>/DME or Li<sub>2</sub>S<sub>6</sub>/DME solutions since the color remained the same level. However, VO<sub>2</sub>(P)-NCNT completely dissolved Li<sub>2</sub>S<sub>4</sub> or Li<sub>2</sub>S<sub>6</sub> and the solutions became transparent. The obvious contrast suggests a strong affinity between Li<sub>2</sub>S<sub>4</sub>/Li<sub>2</sub>S<sub>6</sub> and VO<sub>2</sub>(P) with chemical bonding. Additional visual observation tests in terms of disassembled separators further verify that

LiPS dissolution into the electrolyte was effectively mitigated by the VO<sub>2</sub>(P)-involved cathode. (Fig. S15).

To further identify the LiPS conversion catalyst with VO<sub>2</sub>(P), symmetrical cells with two identical electrodes were designed (Fig. 6b). The electrolytes without the addition of Li<sub>2</sub>S<sub>6</sub> were also compared. For symmetrical batteries without Li<sub>2</sub>S<sub>6</sub>, the current densities of VO<sub>2</sub>(P)-NCNT electrodes are negligible, which implied that the polarization profiles were mainly derived from the redox current of Li<sub>2</sub>S<sub>6</sub> (capacitive current caused by the symmetrical electrodes are negligible). For symmetrical batteries with Li<sub>2</sub>S<sub>6</sub>, it can be clearly observed that the current density of VO<sub>2</sub>(P)-NCNT electrodes were much larger with obvious redox peaks, demonstrating that VO<sub>2</sub>(P) not only electrochemically interact with LiPS but also catalyze the conversion of LiPS. The increased redox current of VO<sub>2</sub>(P)-NCNT electrode under a polarization of ± 1.0 V was in good accordance with the EIS results (Fig. S16).

We used X-ray absorption near-edge spectroscopy (XANES), electron energy-loss spectra (EELS), and XPS to determine the variations in the catalyzed polysulfide chains produced by the VO<sub>2</sub>(P)-NCNT host. To

**Fig. 4.** (a) Cyclic voltammograms at a scanning rate of  $0.1 \text{ mV s}^{-1}$ ; (b) Comparison of the onset potentials and the derived exchange current densities for lithiation/delithiation reactions. (c) EIS curves; (d) The relationship between  $Z'$  and  $\omega^{-1/2}$  with frequency range between 1 and 0.01 Hz before/after cycling (symbols, real data; lines, fitting curves) (e) GITT curves for first charge/discharge process; (f) reaction resistances during the charge/discharge process of NCNT/S and  $\text{VO}_2(\text{P})\text{-NCNT/S}$  cathodes.

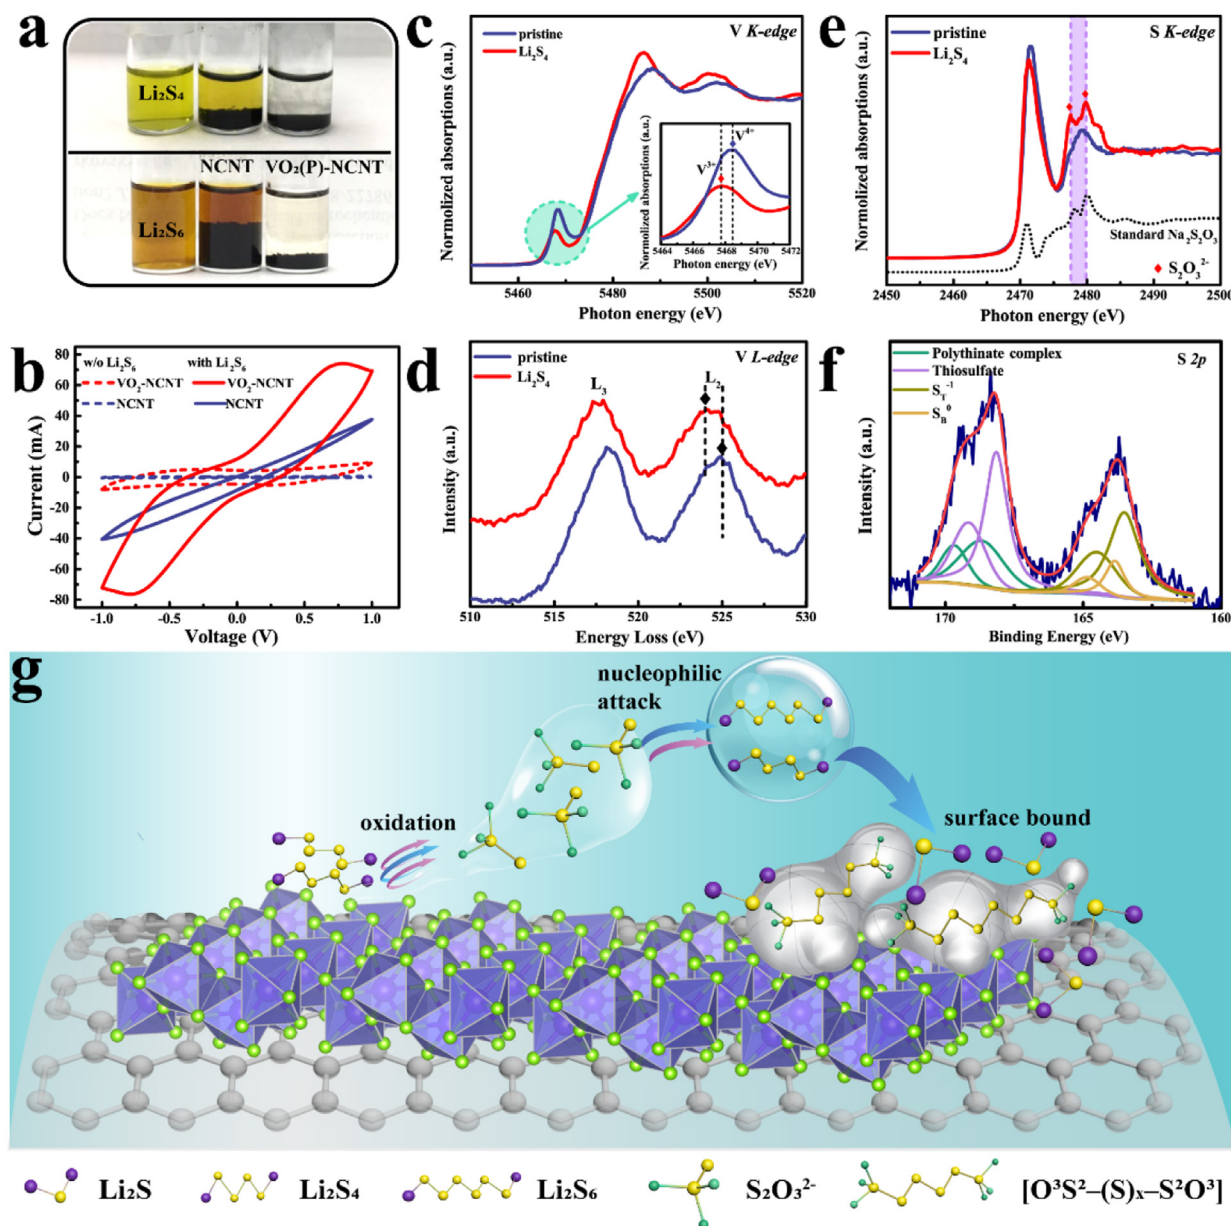

avoid the interference derived from functional groups and charge/discharge products in the electrolyte, we used  $\text{Li}_2\text{S}_4$ , a probe species that represents a polysulfide at an average depth of discharge, to investigate the products. In Fig. 6c, V K-edge peaks shift to a lower energy after soaking in  $\text{Li}_2\text{S}_4\text{-DME}$  solution. The enlarged Fig. (inset of Fig. 6c) shows that the pre-edge peak shifts from 5468.46 to 5467.75 eV, indicating that the  $\text{V}^{4+}$  in  $\text{VO}_2(\text{P})$  is partly reduced to  $\text{V}^{3+}$ . The V K-edge of standard commercial  $\text{V}_2\text{O}_3$  is shown in Fig. S17, which is consistent with the peak position of  $\text{VO}_2(\text{P})\text{-NCNT/Li}_2\text{S}_4$ . Similarly, the V  $L_3$ -edge of EELS shifts from 524.9 to 523 eV, indicating that the valance of vanadium shifts to a lower state (Fig. 6d) [45]. Compared with the pristine state, two new peaks appear at 2478.8 and 2479.9 eV in the sulfur K-edge curves, which correspond to the thiosulfate ( $\text{S}_2\text{O}_3^{2-}$ ) [60]. These two peaks are adequately verified by the curve of standard commercial  $\text{Na}_2\text{S}_2\text{O}_3$  (inset in Fig. 6e). Similarly, the S 2p peaks of  $\text{VO}_2(\text{P})\text{-NCNT/Li}_2\text{S}_4$  (2p<sub>3/2</sub> at 168.2 eV, 2p<sub>1/2</sub> at 167.1 eV) are also attributed to  $\text{S}_2\text{O}_3^{2-}$  (Fig. 6f) [61]. In this case,  $\text{VO}_2(\text{P})$  particles that

are attached to conductive NCNT arrays provide access for electric charge to reach the  $\text{VO}_2(\text{P})\text{-LiPS}$  interface and to trigger LiPS redox reactions. As reported by the previous references [11,35], elemental sulfur undergoes nucleophilic attack by  $\text{S}_2\text{O}_3^{2-}$  and form chains of LiPS or polythionate complexes, which is known as the ‘Wackenroder reaction’. In this way, the insoluble  $\text{S}_2\text{O}_3^{2-}$  that forms on the surface acts as an internal mediator to anchor long-chain LiPS from solution and to trigger conversion to low-order  $\text{Li}_2\text{S}_2/\text{Li}_2\text{S}$  [35].

The schematic illustration of  $\text{VO}_2(\text{P})$  driving LiPS conversion by thiosulfate–polythionate with appropriate redox potentials are summarized in Fig. 6g. First,  $\text{VO}_2(\text{P})$  nanoparticles act as catalysts to oxidize the LiPS to produce thiosulfate due to the strong interaction between  $\text{VO}_2(\text{P})$  and LiPS. Second, thiosulfates act as a mediator to catenate long-chain  $\text{Li}_2\text{S}_x$  ( $x \geq 4$ ) and produce short-chain  $\text{Li}_2\text{S}_2/\text{Li}_2\text{S}$  and surface-bound polythionate complexes. Thus, the  $\text{VO}_2(\text{P})$  plays a vital role in LiPS conversion to polythionate [ $\text{O}_3\text{S}_2\text{(S)}_x\text{-S}_2\text{O}_3$ ] to suppress the LiPS shuttle reactions, resulting in Li-S batteries with superior

performance.

#### 4. Conclusion

A composite host consisting of uniform VO<sub>2</sub>(P) nanoparticles grown on parallel NCNT arrays result in a 3D free-standing hierarchical structure. In this host, VO<sub>2</sub>(P) nanoparticles not only accelerate the charge transfer and ion diffusion with fast redox kinetics but also catalyze the conversion of soluble long-chain LiPS to insoluble polythionate complexes and short-chain Li<sub>2</sub>S<sub>2</sub>/Li<sub>2</sub>S, thus effectively suppressing the shuttle reaction for stable cycling performance. The VO<sub>2</sub>(P)-NCNT/S cathodes exhibits excellent performance with high reversible discharge capacity ( $\approx 1200$  mA h g<sup>-1</sup> at 0.2 C), stable long-term cycling ( $\approx 67\%$  retention at 2 C for 500 cycles), and high sulfur loading cycling (initial areal capacity of 10.2 mA h cm<sup>-2</sup> at 0.2 C for 200 cycles). This study demonstrates that the introduction of VO<sub>2</sub>(P)

enables the design of high loading sulfur-based cathodes with high performance by catalyzing the conversion of LiPS, and has potential applications for the development of practical Li-S batteries.

**Jianneng Liang** is currently a Ph.D. candidate in the department of Mechanical and Materials Engineering at the University of Western Ontario, Canada. He got his B.S. in metallurgical engineering in 2015 from Central South University, China. Currently, his research interests include solid-state polymer electrolytes, hybrid electrolyte, all-solid-state LIBs and Li-S batteries, and the interfacial study in all-solid-state batteries.

**Dr. Qian Sun** is a postdoctoral associate in Prof. Xueliang (Andy) Sun's Group at the University of Western Ontario (Western University), Canada. He received his B.S. degree in Chemistry in 2006, M.S. degree in Physical Chemistry in 2009, and Ph.D. degree in Applied Chemistry in 2013 under the supervision of Prof. Dr. Zheng-Wen Fu on the study of Li-/Na-ion batteries and Na-air batteries, all at Fudan University, China. He joined Prof. Sun's group in 2013 and his current research interests focus on Na-air, Na-ion, and room temperature Na-S batteries as well as solid-state Li/Na batteries.

**Dr. Jianwen Liang** received his Ph.D. degree in inorganic chemistry from University of Science and Technology of China in 2015. He is currently a postdoctoral fellow in Prof. Xueliang (Andy) Sun's Nanomaterials and Energy Group at the University of Western Ontario, Canada. His research interests include sulfide-based solid-state electrolyte as well as all-solid-state Li/Li-ion batteries.

**Sizhe Wang** is currently a Ph.D. candidate at School of materials and energy, University of Electronic Science and Technology of China (UESTC), China. At the same time, he is a visiting student in Prof. Xueliang (Andy) Sun's Nanomaterials and Energy Group at University of Western Ontario, Canada. He got his B.S. degree in Electronics Science and Technology from School of Microelectronics and Solid-State Electronics, UESTC, in 2013. Currently, his research interests focus on nanocarbon and advanced functional materials as well as their applications in energy conversion and storage, especially for Na/Li-ion batteries and Li-S batteries.

**Prof. Jiakuan Liao** is working as a Full professor and a Ph.D. supervisor in University of Electronic Science and Technology of China (UESTC), China. He received his Ph.D. in Materials Science and Engineering in 2001 from Harbin Institute of Technology, and worked as a postdoctoral fellow at Lanzhou Institute of Chemical Physics of Chinese Academy of Sciences in 2003. His current research interests are focused on electronic information materials and devices, electronic functional materials and devices, electronic thin films and integrated devices and new energy materials and devices.

**Feipeng Zhao** is currently a Ph.D. candidate in Prof. Xueliang (Andy) Sun's Group at the University of Western Ontario, Canada. He received his B.S. degree and M.S. degree in Materials Science from Soochow University in 2017 and 2014, respectively. Currently, he is working on the synthesis and characterization of sulfide electrolytes, and development of high-performance solid-state Li metal and Na metal batteries.

**Dr. Xiaofei Yang** is currently a postdoctoral associate in Prof. Xueliang (Andy) Sun's Nanomaterials and Energy Group. He received his B.E. degree in Chemical Engineering from Anhui University, China, in 2013 and Ph.D. degree in Dalian Institute of Chemical Physics, Chinese Academy of Sciences, China, in 2018 under the supervision of Prof. Huamin Zhang. His research interests focus on Li-S batteries, all-solid-state Li-S batteries and battery interface studies via synchrotron X-ray characterizations.

**Alicia Koo** received her B.Sc. in Chemistry at the University of British Columbia in 2016. Her research interests include energy conversion and storage materials for green energy applications. In addition, she is an avid science communicator and advocate for women in STEM.

**Fanpeng Kong** is currently a Ph.D. candidate under the supervision of Prof. Geping Yin in Harbin Institute of Technology (HIT), China. At the same time, he is a visiting student at Prof. Xueliang (Andy) Sun's Advanced Materials for Clean Energy Group, Western University, Canada. He received his B.E. at HIT in 2014, and then joined Prof. Geping Yin's group at HIT. His current research interest focuses on the design and preparation of single atom and nanomaterials for oxygen reduction, hydrogen evolution and organic small molecular oxidation.

**Dr. Shize Yang** received his Ph.D. degree in condensed matter physics from Peking University in 2014 and then worked as postdoc at Oak Ridge National Laboratory and Brookhaven National Laboratory. His current research interests are focused on electron microscopy techniques including aberration corrected scanning transmission electron microscopy, multidimensional electron tomography, cryogenic electron microscopy and in-situ/environmental electron microscopy. The related material systems range from 2D dimensional monolayers, oxide nanoparticles and metal alloys for applications in energy conversion, catalysis and electronic devices.

**Yao Yao** is currently a Ph.D. candidate in National and Local Joint Engineering Laboratory for Lithium-ion Batteries and Materials Preparation Technology at Kunming University of Science and Technology, China. He received his B.S. degree and M.S. degree in Physical Chemistry of Metallurgy from Kunming University of Science and Technology (Kunming, China) in 2012 and 2016, respectively. As a visiting student, he studied in Prof. Xueliang (Andy) Sun's Group at the University of Western Ontario from 2017 to 2018. His current research interests focus on surface modification of electrode materials for lithium/sodium ion batteries.

**Ruying Li** is a research engineer at Prof. Xueliang (Andy) Sun's Nanomaterial and Energy Group at the University of Western Ontario, Canada. She received her master in Material Chemistry under the direction of Prof. George Thompson in 1999 at University of Manchester, UK, followed by work as a research assistant under the direction of Prof. Keith Mitchell at the University of British Columbia and under the direction of Prof. Jean-Pol Dodelet at l'Institut national de la recherche Scientifique (INRS), Canada. Her current research interests are associated with synthesis and characterization of nanomaterials for electrochemical energy storage and conversion.

**Xuejie Gao** is currently a Ph.D. candidate in Prof. Xueliang (Andy) Sun's group at the University of Western Ontario, Canada. She received her B.S. degree in chemistry in 2014 from Ludong University and obtained her M.S. degree in Chemistry in 2017 from Soochow University. Currently, her research interests focus on the development of 3D printing applied for lithium batteries. She is also co-supervised by Prof. T. K. Sham from Chemistry Department in the University of Western Ontario. Part of her work is related to the study of energy materials via synchrotron radiation.

**Prof. Xueliang (Andy) Sun** is a Canada Research Chair in Development of Nanomaterials for Clean Energy, Fellow of the Royal Society of Canada and Canadian Academy of Engineering and Full Professor at the University of Western Ontario, Canada. Dr. Sun received his Ph.D. in materials chemistry in 1999 from the University of Manchester, UK, which he followed up by working as a postdoctoral fellow at the University of British Columbia, Canada and as a Research Associate at l'Institut National de la Recherche Scientifique (INRS), Canada. His current research interests are focused on advanced materials for electrochemical energy storage and conversion, including electrocatalysis in fuel cells and electrodes in lithium-ion batteries and metal-

air batteries.

**Prof. Mengqiang Wu** is a director of the Center for Advanced Electric Energy Technologies within the School of Materials and Energy and Full Professor at the University of Electronic Science and Technology of China (UESTC), China. He received his M.S. degree in Physical Chemistry from Sichuan University, China and Ph.D. in Microelectronics and Solid-State Electronics from UESTC in 1995 and 2002, respectively. He has been working as a visiting scientist within the University of Cambridge, UK and the University of Nottingham, UK, respectively, and a postdoctoral fellow at the University of Southampton, UK. His current research interests are focused on advanced materials for electrochemical energy storage and conversion, electrodes in lithium-ion batteries, supercapacitors and alkali metal-chalcogen

batteries.
